

ENDLESS VISION AND LIMITLESS CONTROL

SAKSHAM RAJ

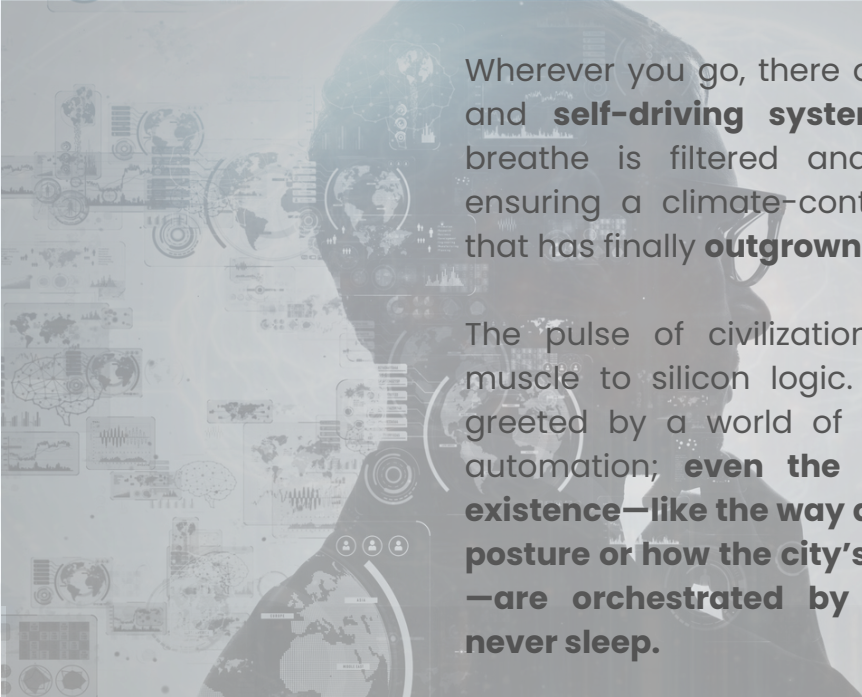

**In a world of endless vision, can we still have secrets?
In a world of limitless control, can we still have surprises?
Your Brain is gonna be ONLINE, just like Computer Networks.**

The **world isn't Hen's Egg**, its very vast and it won't require your permission either to expand! The world is moving veritably presto and its not possible to prognosticate what's gonna be hereafter. The people sounded tensed, frustrated, and exhausted. They're working veritably hard to survive and feed themselves. The competition is veritably high, not because people are willing to work more on lower pay but because of the extreme survival conditions when the person demanding services are robots awaiting honesty, translucency, and thickness from humans.

The process of evolution is very complex. Humans are the dominating species on the globe due to a unique combination of high-level cognitive abilities, complex language, advanced social cooperation, and biology. Unlike other species, humans adapted to varied environments through tool use, technology, and widespread knowledge sharing.

"Anything that allows an organism to get energy more efficiently is going to have huge effects on the evolutionary trajectory of that organism," explains **Prof Rachel Carmody** of Harvard University in Cambridge, Massachusetts.

Wherever you go, there are only **robots, automation, and self-driving systems**. Even the very air we breathe is filtered and monitored by **nanobots**, ensuring a climate-controlled existence in a world that has finally **outgrown its manual origins**.

The pulse of civilization has shifted from human muscle to silicon logic. Wherever you go, you are greeted by a world of tireless robots and invisible automation; **even the most mundane details of existence—like the way a park bench adjusts to your posture or how the city's climate is micro-managed—are orchestrated by self-driving systems that never sleep.**

Someone just witnessed a historic pivot: **AI research has effectively decoupled productivity from human presence**. While this shift displaces traditional employment, it grants corporations unprecedented output and gifts humanity a collective '**time wealth**' measured in billions of hours. The ultimate objective of **Super-Intelligence** is to finalize this transition—relegating manual and cognitive labor to a seamless network of **GPTs** and **humanoid robots**, leaving humans to navigate a world where effort is optional.

After waking up, I just realised it was a **dream to reality**. Currently, humans are using AI for their benefit but as the technology progresses and in a couple of decades an environment shall be there where humans would not be able to control AI systems and if AI has the **capability** to do all the **task itself** and **heal itself**. AI robots will have their own societies, environment, and unnecessary resource; humans. Then why will they obey human's orders? They shall have become competent enough. They will use humans for their work and there will be no choice for those who do not focus on upskilling themselves heavily. Mediocre won't survive long.

"No one knows how to control AIs that are vastly more competent than any human, yet we are getting closer and closer to developing them, with many experts expecting superintelligence in the next five years, at the current pace. This is why leading AI scientists warn that developing superintelligence-AI that outperforms humans across all cognitive tasks—could result in humanity's extinction." as stated in TIME International Magazine.

The Big Question

As we move toward this "**Super-Intelligent**" world, the real research is shifting from "**How do we build it?**" to "**What do we do with the humans who are left with such a huge population?**"
